First Version - August 29, 2016

Present Version - September 19, 2020

# Review of Statistics

What is Statistics?

Do mean earnings differ from men and women, and if so, by how much?

One way to answer this question would be to perform an exhaustive survey of the population measuring the earnings of **each** worker. And, next comparing the mean, for example.

Do mean earnings differ from men and women, and if so, by how much?

One way to answer this question would be to perform an exhaustive survey of the population measuring the earnings of **each** worker. And, next comparing the mean, for example.

# Review of Statistics

The key insight of statistics is that one can learn about the population distribution of earnings simply by selecting a **random sample** rather than survey the entire population.

This is called "**to draw statistical inferences** about the population".

# Review of Statistics

The key insight of statistics is that one can learn about the population distribution of earnings simply by selecting a **random sample** rather than survey the entire population.

This is called "**to draw statistical inferences** about the population".

# Section 1

## Estimation

# Estimators

Assume that:

- $Y$  is a random variable whose unknown mean and variance are  $\mu_Y$  and  $\sigma_Y^2$ ;
- unfortunately you do not have access to the entire population but only to a random sample of  $n$  i.i.d observations  $Y_1, \dots, Y_n$  drawn from it.

How do you exploit the information contained in the sample to guess the true unknown value of  $\mu_Y$ ?

# Estimators

- A first "natural" way to answer this question would be to compute the sample average  $\bar{Y}$ .
- This is not the only way. One could simply use the first observation  $Y_1$  or the last one  $Y_n$ . Alternatively one could take the central one  $Y_{\frac{n+1}{2}}$ .
- In principle any function of the  $n$  components can be used to guess the true value of  $\mu_Y$ .

An **estimator** is a function of  $Y_1, \dots, Y_n$  representing a random draw from a population.

# Terminology

To avoid confusion keep in mind that

- because of the randomness in selecting the sample an estimator is a random variable (with its proper distribution, mean, variance etc...).
- an **estimate** is the numerical value of the estimator when it is actually computed using data from a realized sample. An estimate is a nonrandom number.

# Properties of an estimator

Since there are many possible estimators for an unknown  $\mu_Y$ , how can we choose among them which are to be considered "good" or "better"?

In general we would like

- an estimator to get as close as possible to the unknown true value, at least in some average sense;
- the sampling distribution of an estimator to be as tightly centered on the unknown value as possible.

# Properties of an estimator

Suppose you evaluate an estimator many times over different random samples:

It is reasonable to hope that, in expected value, you would get the correct value.

**Unbiasedness.** Let  $\hat{\mu}_Y$  be an estimator for  $\mu_Y$ , then  $\hat{\mu}_Y$  is unbiased if

$$E(\hat{\mu}_Y) = \mu_Y ,$$

where  $E(\hat{\mu}_Y)$  is the mean of the sampling distribution of  $\hat{\mu}_Y$ .

**example.** The sample average is an unbiased estimator of  $\mu_Y$  if the sample is random.

It is reasonable to hope that, in expected value, you would get the correct value.

**Unbiasedness.** Let  $\hat{\mu}_Y$  be an estimator for  $\mu_Y$ , then  $\hat{\mu}_Y$  is unbiased if

$$E(\hat{\mu}_Y) = \mu_Y ,$$

where  $E(\hat{\mu}_Y)$  is the mean of the sampling distribution of  $\hat{\mu}_Y$ .

**example.** The sample average is an unbiased estimator of  $\mu_Y$  if the sample is random.

It is desirable that when the sample size is large the uncertainty about the value of  $\mu_Y$  arising from random variations in the sample becomes very small. Formally,

**Consistency.** Let  $\hat{\mu}_Y$  be an estimator for  $\mu_Y$ , then  $\hat{\mu}_Y$  is consistent for  $\mu_Y$  if when  $n \rightarrow \infty$

$$\hat{\mu}_Y \xrightarrow{P} \mu_Y ,$$

where  $\xrightarrow{P}$  means converge in probability.

**example.** The sample average is a consistent estimator of  $\mu_Y$  if the sample is random.

It is desirable that when the sample size is large the uncertainty about the value of  $\mu_Y$  arising from random variations in the sample becomes very small. Formally,

**Consistency.** Let  $\hat{\mu}_Y$  be an estimator for  $\mu_Y$ , then  $\hat{\mu}_Y$  is consistent for  $\mu_Y$  if when  $n \rightarrow \infty$

$$\hat{\mu}_Y \xrightarrow{P} \mu_Y ,$$

where  $\xrightarrow{P}$  means converge in probability.

**example.** The sample average is a consistent estimator of  $\mu_Y$  if the sample is random.

Among unbiased estimators it is reasonable to pick the estimator with the tightest sampling distribution.

**Efficiency.** If  $\hat{\mu}_Y$  and  $\bar{\mu}_Y$  are two unbiased estimators for  $\mu_Y$ , then  $\hat{\mu}_Y$  is said to be more efficient than  $\bar{\mu}_Y$  if

$$\text{var}(\hat{\mu}_Y) < \text{var}(\bar{\mu}_Y) .$$

Among unbiased estimators it is reasonable to pick the estimator with the tightest sampling distribution.

**Efficiency.** If  $\hat{\mu}_Y$  and  $\bar{\mu}_Y$  are two unbiased estimators for  $\mu_Y$ , then  $\hat{\mu}_Y$  is said to be more efficient than  $\bar{\mu}_Y$  if

$$\text{var}(\hat{\mu}_Y) < \text{var}(\bar{\mu}_Y) .$$

**Example.** Assume  $Y$  is a random variable normally distributed with the mean equal to  $\mu_Y$  and the variance to  $\sigma_Y^2$ . We consider in turn two different estimators for  $\mu_Y$

- $\bar{Y}$ , which we know is unbiased and consistent for  $\mu_Y$ ;
- $\bar{Y} + \frac{1}{n}$ .

First,

- $E[\bar{Y} + \frac{1}{n}] = \mu_Y + \frac{1}{n}$ , showing that this estimator is biased;  
 $\frac{1}{n}$  represents the bias;
- when  $n$  grows larger  $\bar{Y} + \frac{1}{n}$  tends to  $\mu_Y$  since  $\bar{Y}$  tends to  $\mu_Y$  for the lln while  $\frac{1}{n}$  to 0.

Second,  $\text{VAR}[\bar{Y}] = \text{VAR}[\bar{Y} + \frac{1}{n}] = \frac{\sigma^2}{n}$ .

**Example.** Assume  $Y$  is a random variable normally distributed with the mean equal to  $\mu_Y$  and the variance to  $\sigma_Y^2$ . We consider in turn two different estimators for  $\mu_Y$

- $\bar{Y}$ , which we know is unbiased and consistent for  $\mu_Y$ ;
- $\bar{Y} + \frac{1}{n}$ .

First,

- $E[\bar{Y} + \frac{1}{n}] = \mu_Y + \frac{1}{n}$ , showing that this estimator is biased;  
 $\frac{1}{n}$  represents the bias;
- when  $n$  grows larger  $\bar{Y} + \frac{1}{n}$  tends to  $\mu_Y$  since  $\bar{Y}$  tends to  $\mu_Y$  for the lln while  $\frac{1}{n}$  to 0.

Second,  $\text{VAR}[\bar{Y}] = \text{VAR}[\bar{Y} + \frac{1}{n}] = \frac{\sigma^2}{n}$ .

**Example.** Assume  $Y$  is a random variable normally distributed with the mean equal to  $\mu_Y$  and the variance to  $\sigma_Y^2$ . We consider in turn two different estimators for  $\mu_Y$

- $\bar{Y}$ , which we know is unbiased and consistent for  $\mu_Y$ ;
- $\bar{Y} + \frac{1}{n}$ .

First,

- $E[\bar{Y} + \frac{1}{n}] = \mu_Y + \frac{1}{n}$ , showing that this estimator is biased;  
 $\frac{1}{n}$  represents the bias;
- when  $n$  grows larger  $\bar{Y} + \frac{1}{n}$  tends to  $\mu_Y$  since  $\bar{Y}$  tends to  $\mu_Y$  for the lln while  $\frac{1}{n}$  to 0.

Second,  $\text{VAR}[\bar{Y}] = \text{VAR}[\bar{Y} + \frac{1}{n}] = \frac{\sigma^2}{n}$ .

$\bar{Y}$ 

$$\bar{Y} + \frac{1}{n}$$

**Exercise 1.** Let  $Y$  be a rv with mean  $\mu_Y$  and variance  $\sigma_Y^2$ . Consider an iid random sample  $Y_1, Y_2, \dots, Y_n$ .

**Exercise 1.** Let  $Y$  be a rv with mean  $\mu_Y$  and variance  $\sigma_Y^2$ . Consider an iid random sample  $Y_1, Y_2, \dots, Y_n$ . Prove that as an estimator of  $\mu_Y$  the sample average  $\bar{Y}$  is

- the most **efficient** among those that are weighted averages of  $Y_1, \dots, Y_n$ . [To see the intuition compare  $\bar{Y}$ ,  $Y_1$  and  $\hat{Y} = \frac{1}{n}(\frac{1}{2}Y_1 + \frac{3}{2}Y_2 + \dots + \frac{1}{2}Y_{n-1} + \frac{3}{2}Y_n)$ ]
- the least squares estimator for  $\mu_Y$ .

## Estimator for $\mu_Y$

To estimate  $\mu_Y$  we use  $\bar{Y}$  since it is the Best Linear Unbiased Estimator for  $\mu_Y$ . It is a BLUE estimator.

## Estimator for $\mu_Y$

To estimate  $\mu_Y$  we use  $\bar{Y}$  since it is the Best Linear Unbiased Estimator for  $\mu_Y$ . It is a BLUE estimator.

**Remark.** Remember that everything holds only in case of random samples. For nonrandom samples  $\bar{Y}$  is typically biased.

## Estimator for $\sigma_Y^2$

Let  $Y$  be a rv with mean  $\mu_Y$  and variance  $\sigma_Y^2$ . Show that the sample variance

$$s_Y^2 = \frac{1}{n} \sum_i (Y_i - \bar{Y})^2 .$$

is a biased estimator for  $\sigma_Y^2$  and propose an unbiased alternative.

## Estimator for $\sigma_Y^2$

The corrected sample variance  $s_Y^2$ , defined as

$$s_Y^2 = \frac{1}{n-1} \sum_i (Y_i - \bar{Y})^2$$

is an **unbiased** and **consistent** estimator of the population variance  $\sigma_Y^2$ . Note:

- the population mean  $\mu_Y$  is replaced by the sample mean  $\bar{Y}$ .
- instead of  $n$  we divide by  $(n-1)$ . This is due to the fact that using  $\bar{Y}$  instead of  $\mu_Y$  introduces a small downward bias in  $(Y_i - \bar{Y})^2$  that is corrected by dividing by  $n-1$ .

## Estimator for $\sigma_Y^2$

**Remark.** Dividing by  $(n-1)$  is called a **degrees of freedom correction**: estimating the mean uses up 1 degree of freedom of the data (part of the info contained in the sample) and only  $n-1$  are left.

## The standard error of $\bar{Y}$

Since

- the standard deviation of the sampling distribution of  $\bar{Y}$  is  $\sigma_{\bar{Y}} = \sigma_Y / \sqrt{n}$ ;
- $s_Y^2 \xrightarrow{P} \sigma_Y^2$  (consistency) ,

then one is justified using  $s_Y / \sqrt{n}$  as an estimator of  $\sigma_{\bar{Y}}$ .  $s_Y / \sqrt{n}$  is called the **standard error of  $\bar{Y}$**  and is denoted  $SE(\bar{Y})$  or  $\hat{\sigma}_{\bar{Y}}$ .

**Exercise 2.** Consider two rv  $X$  and  $Y$  with means and variance  $\mu_X$ ,  $\sigma_X$  and  $\mu_Y$ ,  $\sigma_Y$  respectively. Let  $\sigma_{XY}$  denote the covariance between  $X$  and  $Y$ . Show that the sample covariance

$$s_{XY} = \frac{1}{n-1} \sum (X_i - \bar{X})(Y_i - \bar{Y}) ,$$

is an unbiased estimator for  $\sigma_{XY}$ .

## Estimator for $\sigma_{XY}$

The corrected sample covariance  $S_{XY}$

$$s_{XY} = \frac{1}{n-1} \sum (X_i - \bar{X})(Y_i - \bar{Y}) ,$$

is an unbiased and consistent estimator for  $\sigma_{XY}$ .

## Section 2

# Parametric Testing

# Introduction and terminology

Statistical testing provides a formal framework in which a researcher can try to answer a yes/no question based on a random sample of data. The two main building blocks of a statistical test are:

- **null hypothesis  $H_0$** , the hypothesis to be tested;
- **alternative hypothesis  $H_1$** , the hypothesis against which  $H_0$  is tested.

## Introduction and terminology

	$H_0$ is True	$H_0$ is False
Reject $H_0$	Error type I (False positive)	Correct inference (True positive)
Fail to Reject $H_0$	Correct inference (True negative)	Error type II (False negative)

**Size of the test** is the probability of incorrectly rejecting  $H_0$  when  $H_0$  is true, that is the probability to make a type I error.

**Power of the test** is the probability of correctly rejecting  $H_0$  when  $H_0$  is false.

## Subsection 1

Hypothesis tests concerning the population mean

The null hypothesis  $H_0$  is that the population mean  $E(Y) = \mu_Y$  takes on a specific value denoted  $\mu_0$

$$H_0 : E(Y) = \mu_0 .$$

The alternative hypothesis  $H_1$  specifies what is true if the null hypothesis is not.

- The most general alternative hypothesis is

$$H_1 : E(Y) \neq \mu_0 ,$$

known as the **two-sided alternative hypothesis** because it allows  $E(Y)$  to be either less or greater than  $\mu_0$ ;

- other specifications of the alternative hypothesis are, for example,

$$H_1 : E(Y) \geq \mu_0 \quad \text{or} \quad H_1 : E(Y) \leq \mu_0$$

known as the **one-sided alternative hypothesis**.

The problem we face is to use the information contained in a random sample to decide if we

- reject  $H_0$

- fail to reject  $H_0$  since we do not have enough evidence against it. This is  $\neq$  from accepting  $H_0$ .

- In any give sample  $Y_1, \dots, Y_n$  the sample average  $\bar{Y}$  is in general different from the hypothesized value  $\mu_0$ .

This is caused by either the following two reasons:

- the true  $\mu_Y \neq \mu_0$  ( $H_0$  is false);
  - because of the random sampling.
- 
- Sadly it is impossible to distinguish between these two possibilities **with certainty**.

However it is possible to do a probabilistic calculation that permits testing  $H_0$  in a way that accounts for sampling uncertainty.

- This calculation involves using the data to compute the **p-value** associated with  $H_0$ .

## p-value (intuition)

Let's consider a random sample of students drawn from this class. The average age  $\bar{Y}$  of the sample is 23.4. Assume that the null hypothesis we would like to test is  $H_0 : E(Y) = 22$ .

The p-value associated with  $H_0$  is the probability of drawing a value of  $\bar{Y}$  at least as different from 22 as the observed value of 23.4 by pure random sampling variation and assuming that  $H_0$  is true.

## p-value (intuition)

Let's consider a random sample of students drawn from this class. The average age  $\bar{Y}$  of the sample is 23.4. Assume that the null hypothesis we would like to test is  $H_0 : E(Y) = 22$ .

The p-value associated with  $H_0$  is the probability of drawing a value of  $\bar{Y}$  at least as different from 22 as the observed value of 23.4 by pure random sampling variation and **assuming that  $H_0$  is true**.

## p-value (intuition)

If the probability of drawing a value of  $Y$  at least as different from 22 as the observed value of 23.4 by pure random sampling variation (namely the **p-value**)

- is **large**, say 0.5, it means that under  $H_0$  it would be likely to draw 23.4;
- is **small**, say 0.05, it means that under  $H_0$  it would be very unlikely to draw 23.4;

## p-value (intuition)

If the probability of drawing a value of  $Y$  at least as different from 22 as the observed value of 23.4 by pure random sampling variation (namely the **p-value**)

- is **large**, say 0.5, it means that under  $H_0$  it would be likely to draw 23.4; **[UNREASONABLE to REJECT  $H_0$ ]**;
- is **small**, say 0.05, it means that under  $H_0$  it would be very unlikely to draw 23.4; **[REASONABLE to REJECT  $H_0$ ]**.

## p-value (definition)

Let

- $\bar{Y}^{\text{act}}$  be the value of the sample average actually computed with the sample at hand
- $\Pr_{H_0}$  be the probability computed under the null hypothesis (that is computed assuming that  $E(Y_i) = \mu_0$ ).

**p-Value.** The p-value is defined as

$$\text{p-value} = \Pr_{H_0} \left[ |\bar{Y} - \mu_0| > |\bar{Y}^{\text{act}} - \mu_0| \right] .$$

## p-value (definition)

Let

- $\bar{Y}^{\text{act}}$  be the value of the sample average actually computed with the sample at hand
- $\Pr_{H_0}$  be the probability computed under the null hypothesis (that is computed assuming that  $E(Y_i) = \mu_0$ ).

**p-Value.** The p-value is defined as

$$\text{p-value} = \Pr_{H_0} \left[ |\bar{Y} - \mu_0| > |\bar{Y}^{\text{act}} - \mu_0| \right] .$$

**Remark.** For continuous rv this probability is the area in the tails of the distribution, under the null hypothesis, of  $\bar{Y}$  beyond  $\mu_0 \pm |\bar{Y}^{\text{act}} - \mu_0|$ .

**Remark.** Hence to calculate the p-value we need to know what is the distribution of  $\bar{Y}$  under the null hypothesis  $H_0$ . Since you master the CLT, this is not a problem anymore at least when  $n$  is large.

## p-value (computation when $\sigma_{\bar{Y}}^2$ is known)

When  $n$  is large, under the null hypothesis  $H_0 : E(Y) = \mu_0$

$$\bar{Y} \xrightarrow{d} N\left(\mu_0, \frac{\sigma_{\bar{Y}}^2}{n}\right) ,$$

where  $\sigma_{\bar{Y}}^2 = \frac{\sigma_Y^2}{n}$  is known by assumption. Then,

$$\frac{\bar{Y} - \mu_0}{\sqrt{\frac{\sigma_{\bar{Y}}^2}{n}}} \xrightarrow{d} N(0, 1) .$$

So the p-value is equivalent to the probability of obtaining  $(\bar{Y} - \mu_0)/\sigma_{\bar{Y}}$  greater than  $(\bar{Y}^{\text{act}} - \mu_0)/\sigma_{\bar{Y}}$  **in absolute value**.

## p-value (computation when $\sigma_Y^2$ is unknown)

When  $\sigma_Y^2$  is unknown the procedure remains essentially the same. We just need to replace  $\sigma_Y^2$  with its consistent estimator  $s_Y^2$ . In this case, again for the CLT,

$$\frac{\bar{Y} - \mu_0}{\sqrt{\frac{s_Y^2}{n}}} = \frac{\bar{Y} - \mu_0}{SE(\bar{Y})} \xrightarrow{d} N(0, 1) ,$$

where  $(\bar{Y} - \mu_0)/SE(\bar{Y})$  has a special name, the **t-statistics** or **t-ratio**.

## Test procedure

In both cases the procedure to test  $H_0 : \mu_Y = \mu_0$  against  $H_1 : \mu_Y \neq \mu_0$  is the same. It consists in three steps:

- based on your sample and under  $H_0$  compute the t-ratio

$$t^{\text{act}} = \frac{\bar{Y}^{\text{act}} - \mu_0}{\text{SE}(\bar{Y})} ;$$

- obtain the corresponding p-value using

$$\text{p-value} = \Pr_{H_0} [ |t| > |t^{\text{act}}| ] ,$$

where, for the CLT,  $t$  is distributed according to  $N(0,1)$ ;

- **decide** if the p-value is sufficiently small to reject  $H_0$ .

# Practice

**Exercise 4.** Consider a random sample drawn from a Normal distribution with unknown mean  $\mu_x$  and variance 1. The sample average  $\bar{X}$  is found to be 5.4.

- Assume  $n=10$  and compute the p-value associated with the test of  $H_0 : \mu_x = 5$  versus  $H_1 : \mu_x \neq 5$ .
- Repeat the exercise for  $n=100$ ,  $n=5$ . Comment.
- Assume  $n=100$  and  $\bar{X} = 7.5$  and compute the p-value associated with the test of  $H_0 : \mu_x = 5$  versus  $H_1 : \mu_x \neq 5$ .
- Assume  $n=10$  and  $\bar{X} = 5.4$  and compute the p-value associated with the test of  $H_0 : \mu_x = 5$  versus  $H_1 : \mu_x < 5$ .

## Subsection 2

Hypothesis test with a pre-specified significance level

Typically we give a preferential treatment to the null hypothesis  $H_0$  (Ex. with the legal system). In this case

- type I error:  $H_0$  is true but you reject it (False Positive)

is the most dangerous.

For this reason often we set in advance the probability of making the type I error.

This probability is called **significance level** of the test. With a pre-specified significance level, testing  $H_0$  does not require to **explicitly** calculate the p-value.

Typically we give a preferential treatment to the null hypothesis  $H_0$  (Ex. with the legal system). In this case

- type I error:  $H_0$  is true but you reject it (False Positive)

is the most dangerous.

For this reason often we set in advance the probability of making the type I error.

This probability is called **significance level** of the test. With a pre-specified significance level, testing  $H_0$  does not require to **explicitly** calculate the p-value.

## Test procedure

- set the significance level, say 5%;
- obtain from the statistical table the corresponding **critical value**;  
it is the value for which the area under the tails (left and right) is exactly 5%; in case of a significance level of 5% is  $|1.96|$ . **[visualization]**
- compute the actual value of the t statistics

$$t^{\text{act}} = \frac{\bar{Y}^{\text{act}} - \mu_0}{\text{SE}(\bar{Y})} ,$$

based on the available sample;

- apply the rule

Reject  $H_0$  if  $|t^{\text{act}}| > 1.96$  .

## Confidence intervals (definition)

The rejection rule in a test with 5% significance level reads

Reject  $H_0$  if  $|t| > t_{5\%}$  .

This implies that the set of values associated with **non-rejection** at the 5% level can be written as

$$-t_{5\%} < \frac{\bar{Y} - \mu_Y}{SE(\bar{Y})} < t_{5\%} .$$

As a consequence

$$\bar{Y} - SE(\bar{Y})t_{5\%} < \mu_Y < \bar{Y} + SE(\bar{Y})t_{5\%} .$$

The last interval represents a 95% **confidence interval** for the population mean.

## Confidence intervals (definition)

The rejection rule in a test with 5% significance level reads

Reject  $H_0$  if  $|t| > t_{5\%}$  .

This implies that the set of values associated with **non-rejection** at the 5% level can be written as

$$-t_{5\%} < \frac{\bar{Y} - \mu_Y}{SE(\bar{Y})} < t_{5\%} .$$

As a consequence

$$\bar{Y} - SE(\bar{Y})t_{5\%} < \mu_Y < \bar{Y} + SE(\bar{Y})t_{5\%} .$$

The last interval represents a 95% **confidence interval** for the population mean.

## Confidence intervals (interpretation)

The correct interpretation of a confidence interval is

- **before** the sample is drawn, the random interval has a 95% chance of containing the true  $\mu_Y$ ;
- **after** the sample is drawn either the unknown parameter lies in the interval or it does not! For 95% of random samples, it does.

## Subsection 3

testing the difference between population means

To illustrate this testing procedure:

- let  $\mu_W$  be the mean of  $Y_W$ , a rv representing the hourly earnings of a group of women recently graduated;
- let  $\mu_M$  be the mean of  $Y_M$ , a rv representing the hourly earnings of a group of men recently graduated;
- assume that you have one sample of  $n_M$  men and an independent sample with  $n_W$  women.

We aim at testing the null hypothesis  $H_0 : \mu_M - \mu_W = 0$  against  $H_1 : \mu_M - \mu_W \neq 0$ .

## Comparing means from different populations

Since  $\bar{Y}_M$  and  $\bar{Y}_W$  are constructed from different random samples, they are independent. Then, when  $n_m$  and  $n_w$  are large, invoking the CLT gives

$$\bar{Y}_M - \bar{Y}_W \xrightarrow{d} N\left(\mu_M - \mu_W, \frac{\sigma_M^2}{n_M} + \frac{\sigma_W^2}{n_W}\right) .$$

When  $\sigma_M^2$  and  $\sigma_W^2$  are unknown we can compute the t-ratio for this test as

$$t = \frac{\bar{Y}_m - \bar{Y}_w - d_0}{SE(\bar{Y}_m - \bar{Y}_w)} \xrightarrow{d} N(0, 1) ,$$

where  $SE(\bar{Y}_m - \bar{Y}_w) = \sqrt{\frac{s_m^2}{n_m} + \frac{s_w^2}{n_w}}$  and follow the usual procedure.

**Exercise 5.** Data on fifth grade (math and reading) score for 420 school districts in California yield  $\bar{Y} = 646.2$  and  $S_Y = 19.5$ .

- Build a confidence interval at 95% level for the unknown  $\mu_Y$ .
- When districts are divided into districts with large classes (more than 20 students) and districts with small classes (less than 20 students) we get

	$\bar{Y}$	$S_Y$	n
small	657.4	19.4	238
large	650	17.9	182

Is there statistically significant evidence that districts with smaller classes have higher average test score?

## Subsection 4

why t-ratio?

- If  $n$  is large then the CLT implies that

$$\text{t-ratio} = \frac{\bar{Y} - \mu_0}{\sqrt{\frac{s_Y^2}{n}}} = \frac{\bar{Y} - \mu_0}{\text{SE}(\bar{Y})} \xrightarrow{d} N(0, 1) ,$$

- If  $n$  is small we do not know the distribution of the t-ratio. However if we are willing to assume that  $Y$  is Normally distributed then

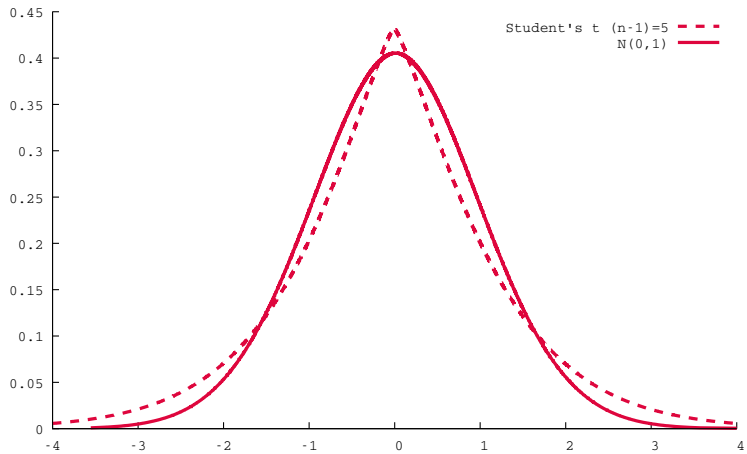

$$\text{t-ratio} = \frac{\bar{Y} - \mu_0}{\sqrt{\frac{s_Y^2}{n}}} = \frac{\bar{Y} - \mu_0}{\text{SE}(\bar{Y})} \sim \text{Student's } t_{(n-1)} .$$

- If **n is large** then the CLT implies that

$$\text{t-ratio} = \frac{\bar{Y} - \mu_0}{\sqrt{\frac{s_Y^2}{n}}} = \frac{\bar{Y} - \mu_0}{\text{SE}(\bar{Y})} \xrightarrow{d} N(0, 1) ,$$

- If **n is small** we do not know the distribution of the t-ratio. However if we are willing to assume that **Y is Normally distributed** then

$$\text{t-ratio} = \frac{\bar{Y} - \mu_0}{\sqrt{\frac{s_Y^2}{n}}} = \frac{\bar{Y} - \mu_0}{\text{SE}(\bar{Y})} \sim \text{Student's } t_{(n-1)} .$$

## Section 3

# Distribution Free Testing

# Distribution free testing

- Usually we test statistical hypothesis with respect to a random variable  $Y$  whose probability distribution  $p(Y)$  is known.
- In many situation, however, we do not know  $p(Y)$  but we need to do inference on the phenomenon summarized by  $Y$ .
- Nonparametric testing procedures fill this gap imposing only two requirements
  1. the phenomenon of interest must be described as a continuous random variable  $Y$ ;
  2. the realizations of  $Y$  must be replaceable with the corresponding **rank**, i.e. with natural numbers  $1, \dots, n$  once they have been ordered.

## Distribution free test

Let's set the stage.

- Let's consider  
 $(Y_1, \dots, Y_n)$ , a sample of  $n$  i.i.d. observations;  
 $(R_1, \dots, R_n)$ , the corresponding ranks .
- As usual, behind a specific random sample and its ranks there are two random variables  $Y$  and  $R$ .
- In particular  $R$  is known as the random variable **Rank**. Note that even if  $Y_1, \dots, Y_n$  are i.i.d.  $R_1, \dots, R_n$  **are not independent** since

$$\sum_{i=1}^n r_i = \frac{n(n+1)}{2} .$$

## Sign Test - Fisher

Let  $\theta_Y$  be the unknown [median] of a continuous rv  $Y$  and  $(Y_1, \dots, Y_n)$  a random sample drawn from the population with the aim of testing  $H_0 : \theta_Y = \theta_0$  against  $H_1 : \theta_Y \neq \theta_0$ .

Under the null hypothesis  $H_0 : \theta_Y = \theta_0$

- $\Pr(Y < \theta_0) = \Pr(Y > \theta_0) = 0.5$  implying that  
 $\Pr(Y_i < \theta_0) = \Pr(Y_i > \theta_0) = 0.5 \quad i = 1, \dots, n$  and  
 $\Pr(D_i < 0) = \Pr(D_i > 0) = 0.5 \quad i = 1, \dots, n$ , where  $D_i = X_i - \theta_0$
- we can define

$$s(d_i) = \begin{cases} 1 & d_i > 0 \\ 0 & d_i < 0 \end{cases},$$

and the associated rv  $S = \sum_i s(d_i)$ .

## Sign Test - Fisher

Let  $\theta_Y$  be the unknown [median] of a continuous rv  $Y$  and  $(Y_1, \dots, Y_n)$  a random sample drawn from the population with the aim of testing  $H_0 : \theta_Y = \theta_0$  against  $H_1 : \theta_Y \neq \theta_0$ .

Under the null hypothesis  $H_0 : \theta_Y = \theta_0$

- $\Pr(Y < \theta_0) = \Pr(Y > \theta_0) = 0.5$  implying that  
 $\Pr(Y_i < \theta_0) = \Pr(Y_i > \theta_0) = 0.5 \quad i = 1, \dots, n$  and  
 $\Pr(D_i < 0) = \Pr(D_i > 0) = 0.5 \quad i = 1, \dots, n$ , where  $D_i = X_i - \theta_0$
- we can define

$$s(d_i) = \begin{cases} 1 & d_i > 0 \\ 0 & d_i < 0 \end{cases},$$

and the associated rv  $S = \sum_i s(d_i)$ .

# Sign Test - Fisher

The intuition behind the test is very simple:

- under  $H_0$ ,  $S^{\text{act}}$  should not be too far away from the mean of the (so far unknown) distribution of  $S$ .
- Then the test procedure is standard and depends on the specification of the alternative hypothesis  $H_1$ , if it is one-sided or two-sided.

**Problem.** It remains to establish what is the distribution of  $S$ . Does it require to specify a distribution for  $Y$ ? Or is it **free from the distribution** of  $Y$ ?

## Sign Test - Fisher

Under  $H_0$  the distribution of  $S$  is given by

$$P(S = 0) = \Pr \left[ \sum_i s(D_i) = 0 \right] = 0.5^n$$

$$P(S = n) = \Pr \left[ \sum_i s(D_i) = n \right] = 0.5^n$$

$$P(S = s) = \binom{n}{s} 0.5^n$$

that is  $S$  is a Binomial rv with parameters  $(n, 0.5)$  and so it is free from the distribution of  $X$ .

**Remark.** If the median of  $Y$  is not  $\theta_0$  but another value  $\theta_1$  then it is not possible to evaluate  $P[(X - \theta_0) > 0]$  and the distribution free property disappears.

## Signed Rank Test - Wilcoxon

Procedure to test  $H_0 : \theta = \theta_0$ , that is the median of a **symmetric** continuous rv  $X$  is equal to  $\theta_0$ . Let

$(x_1, \dots, x_n)$  [sample of  $n$  independent Bernoulli trials]

$(d_1, \dots, d_n)$  [ $d_i = x_i - \theta_0$ ]

$(|d_1|, \dots, |d_n|)$  [absolute values of  $d_i$ ]

$(r_1, \dots, r_n)$  [ranks of  $|d_i|$  ] ,

the Wilcoxon test statistics reads

$$t = \sum_{i=1}^n r_i s(d_i) ,$$

where  $s(d_i) = 1$  if  $d_i > 0$  and  $s(d_i) = 0$  if  $d_i < 0$ .

# Practice

**Exercise 6.** Consider the following random sample with  $n=4$ :  $x_1 = 9$ ,  $x_2 = 0$ ,  $x_3 = -3$  and  $x_4 = 3$ . Assume  $\theta_0 = 5$ . Compute the Wilcoxon test statistics for this sample.

# Distribution of the Wilcoxon statistics

The distribution of  $T$  is in general unknown. But,

## Distribution of the Wilcoxon statistics

Consider a small sample composed by 3 observations  $(x_1, x_2, x_3)$ . Then all the possible combinations of the  $s(d_i)$  values with the corresponding  $t$  can be summarized as follows

Ranks			$t$
1	2	3	
1	1	1	$(1+2+3)=6$
0	1	1	$(2+3)=5$
1	0	1	$(1+3)=4$
1	1	0	$(1+2)=3$
0	0	1	$(3)=3$
0	1	0	$(2)=2$
1	0	0	$(1)=1$
0	0	0	$0(0)=0$

Then the distribution of  $T$  is

$t$	0	1	2	3	4	5	6
$P(T=t)$	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{2}{8}$	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{1}{8}$

## Signed Rank Test - Wilcoxon

In general,

- T assumes values in the range  $[0, \frac{n(n+1)}{2}]$ ;
- T is symmetric around its mean and it is free from the distribution of X;

$$\text{- } E[T] = \sum_{i=1}^n r_i E[s(d_i)] = \sum_{i=1}^n r_i (1\frac{1}{2} + 0\frac{1}{2}) = \frac{n(n+1)}{4}$$

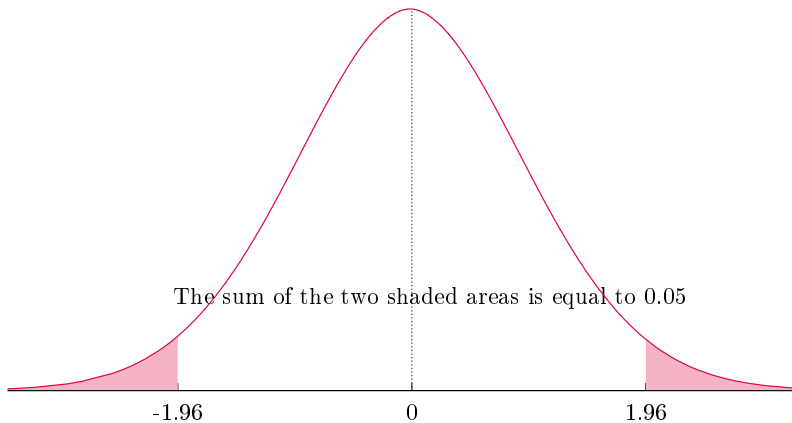

$$\text{- } \text{Var}[T] = \sum_{i=1}^n r_i^2 \text{Var}[s(d_i)] = \sum_{i=1}^n r_i^2 (\frac{1}{2} - \frac{1}{4}) = \frac{n(n+1)(2n+1)}{24}$$

The intuition behind this test is simple: under  $H_0$   $t$  should be close to  $E[T]$  the mean of  $T$  which under symmetry is also the median. The test procedure is then standard.

## Standardized Normal Density

Why the median of  $Y$  and not the mean?

Because when the distribution of  $Y$  is unknown it is always possible to assign the probability to the event  $Y - \theta > 0$ , that is by definition 0.5.

This is not the case for the event  $Y - \mu_Y$ , except when  $Y$  is symmetric.
