

# The Growth of Firms

LEM people (GB PD GD GF MG AS FT)

CO3 dissemination meeting  
Warsaw, 27 June 2009

# Common Dissatisfaction

Lack of relation between theoretical and empirical investigations. . .

**Economics consists of theoretical laws which  
nobody has verified  
and of empirical laws which  
nobody can explain.**

## Recent 'Economics' crisis

### Present crisis predictable and predicted:

- trade unbalance and foreign debt ownership
- low interest rate and demand for financial instruments
- boom in prices, particular houses
- increased level of leverage

$$\text{leverage} = \frac{\text{equity} + \text{debt}}{\text{equity}}$$

### What went wrong? **The economics**

- wrong **pricing models** to build and rate securities
- **heterogeneity** of behaviours and preferences exposes the system to external shocks
- **domino effect**: self-reinforcing mechanism governing the propagation of shocks in financial and (the avalanche or domino effect)

## Recent 'Economics' crisis

Present crisis predictable and predicted:

- trade unbalance and foreign debt ownership
- low interest rate and demand for financial instruments
- boom in prices, particular houses
- increased level of leverage

$$\text{leverage} = \frac{\text{equity} + \text{debt}}{\text{equity}}$$

# Firms Size

We consider  $S_{ij}(t)$  is the size of firm  $i$  in sector  $j$  at time  $t$ . We define the normalized (log) size

$$s_{ij}(t) = \log(S_{ij}(t)) - \langle \log(S_{ij}(t)) \rangle_i .$$

Main results on empirical firms size densities

- Heterogeneity of shapes across sectors
- Bimodality and no log-normality
- Separation core-fringe
- Paretian upper-tails?

# Firms Size

## Input intensity

The amount of **labor**  $L$  (employees) or **capital**  $K$  (tangible assets) necessary to produce a unit of output  $S$ .

How much different  $S/K$  or  $S/L$  can be inside a sector? Estimate the joint density  $\text{Prob}(\log(S/K), \log(S/L))$ .

For any couple of  $(\log(S/K), \log(S/L))$  the height of the surface is proportional to the probability of finding a firm using that amount of inputs.

1997 data. Sales and capital in thousands of Liras (1 Eur  $\sim$  2KL)

## Behaviour of the upper tail

Let  $s_i$  the size of firm  $i$  and let  $s_i = \log(S_i)$  its log,

$$F_S(x) = \text{Prob} \{s \leq x\} = \text{fraction of firms with } \log(\text{size}) \leq x .$$

On a log-log scale

$$\log(1 - F_S(x)) \sim -ax$$

Pareto (Type I) behaviour

$$1 - F_S(x) = \text{Prob} \{S > x\} \sim \left(\frac{S}{S_0}\right)^{-a}$$

## Behaviour of the upper tail

Let  $s_i$  the size of firm  $i$  and let  $s_i = \log(S_i)$  its log,

$$F_S(x) = \text{Prob} \{s \leq x\} = \text{fraction of firms with } \log(\text{size}) \leq x .$$

# The Polya Assignment of Business Events

- 1 Consider an urn with  $N$  different balls, each representing a firm

Draw a ball and replace with **TWO** of the same kind. (Here the first draw from an urn with two types of ball)

- 3 Repeat this procedure  $M$  times

RESULT: partition of  $M$  events on  $N$  firms.

# Occupancy distribution

The “Census of Manufacturers and Services” (ISTAT) contains data on business units and employees, classified with respect to  $L = 784$  geographical locations (local system of labor mobility) and six digits ATECO codes.

Sectoral occupancy distribution  $f_j(n)$  of the  $N_j$  firms of sector  $j$

$f_j(n)$  = number of locations with  $n$  firms of sector  $j$

An **even distribution** would imply  $f_j(n) \sim N_j/L$ .

## Occupancy distribution

# Sectoral occupancy

20 - Wood processing

25 - Rubber and plastic products

28 - Fabricated metal products

33 - Precision instruments

## Detecting the self-reinforcing effect

Assume firms choose where to locate their next plant based on

- the size of the economy (local demand, generic labour availability, infrastructures, ...)
- number of similar plants located there (technological spillover, skilled labour availability, ...)

Probabilistic interpretation

Prob. locate in  $l \sim \beta$  (size of site  $l$ ) +  $b$  (similar firms in  $l$ )

## Sectoral estimates (no metropolitan areas)

## The model is the policy

Empirical investigation detect regularities emerging from heterogeneous behaviour.

These regularities suggest the presence of self-reinforcing effects

Capturing these effect we obtain more reliable description of economic aggregate behaviour.

## The model is the policy

Empirical investigation detect regularities emerging from heterogeneous behaviour.

Capturing these effect we obtain more reliable description of economic aggregate behaviour.

## Q&A

**Q:** Firm crisis prediction: if risk rating does not help, what to use?

**A:** Don't stick to short-term financial conditions, but use also mid-term economic indicators.

**Q:** How economic downturns affect small and large firms?

**A:** Study the evolution of the easily-to-parametrize growth rates distribution and its relation with general economic behaviour . Few firms lead the growth, many absorb negative shocks.

**Q:** How globalization affects the distribution of economic activities?

**A:** Demand-driven or market-driven location decisions are differently affected than decision based on technological advantages.

## Q&A
